

AI Product Management Case Study

Building, Automating & Scaling with AI

As a Product Manager in travel-tech, I have led multiple AI and ML initiatives from ideation to production, focusing on measurable business impact.

Key AI & ML Initiatives

- Built a Rule Recommender PoC that analyzed historical booking, review, and operational data to automatically recommend business rules.
- Developed and evaluated an XGBoost Regressor-based predictive model to forecast business outcomes and support optimization decisions.
- Led a deep learning-based image comparison initiative using embeddings and vector similarity techniques, improving image matching accuracy from ~30% to 90%+.
- Designed an Agentic Personal Assistant integrated with 10+ internal tools and MCPs, delivering approximately 2x productivity gains.
- Defined and launched an AI monitoring and observability dashboard to track model quality, latency, adoption, and business KPIs.

AI-Native Product Development

Over the past few months, my approach to product development has shifted from primarily documenting ideas to actively building and validating them using AI tools such as Cursor. Instead of waiting for formal development cycles, I now prototype concepts, test assumptions, and explore edge cases before finalizing requirements.

AI-assisted workflow distribution:

- 62% — Rapid prototyping and experimentation
- 19% — Automation scripts and tooling
- 17% — Exploring approaches and problem spaces

This shift has enabled me to move ideas from concept to working prototypes within hours rather than weeks, significantly reducing ambiguity before engineering involvement and accelerating product discovery and validation.
